## INTRODUCTION

For the last decade, our laboratory has had great interest in the chemistry of silylarsines [1]. These compounds, in combination with Group 13 alkyl or halogen derivatives, have been shown to be excellent starting reagents for preparing compounds which contain the Group 13 element-arsenic bond. Although the reactivity of silylarsines is well documented (*vide supra*), structural characterization data for these species has been limited to solution- and gas-phase measurements [2] due to their non-crystallinity. As a result, unambiguous structural information for these compounds is scant and appears to be limited to lithium-arsenide salts coordinated to donor solvents [3]. Therefore, we became interested in preparing organosilylarsines which could find utility in our ongoing investigations of Group 13 element-arsenic compounds and be characterized in the solid-state. In addition to this chemistry, we wished to study systems which focused on the reactions of organosilylarsines with Group 13 and Group 16 derivatives. Through our efforts, we have been able to observe some interesting chemical phenomena and isolate several new compounds (this work).

Herein, we report the synthesis and structural characterization of three new organosilylarsine derivatives  $\text{As}(\text{Si}^t\text{BuMe}_2)_3$  (**1**),  $\text{As}(\text{SiMe}_3)_2(\text{SiPh}_3)$  (**2**), and

$\text{Et}_3\text{Ga}\bullet\text{As}(\text{SiMe}_3)_2(\text{SiPh}_3)$  (**3**). The X-ray crystal structure of  $\text{As}(\text{SePh})_3$  (**4**), previously unreported [4], is also detailed.

## EXPERIMENTAL

### *Synthesis*

*General Considerations.* All manipulations of air- and moisture-sensitive materials were performed in a Vacuum Atmospheres HE-493 Dri-Lab containing an argon atmosphere or by general Schlenk techniques. Toluene and pentane were distilled over sodium-potassium alloy under dry dinitrogen. Dimethoxyethyl ether (DME) and diethyl ether were distilled from sodium benzophenone ketyl under dry dinitrogen.  $\text{In}(\text{SePh})_3$  [5] and  $\text{As}(\text{SiMe}_3)_3$  [6] were synthesized by literature procedures.  $\text{LiAs}(\text{SiMe}_3)_2$  [6] was prepared via the 1:1 mole reaction of  $\text{As}(\text{SiMe}_3)_3$  and  $\text{MeLi}$ . Sodium-potassium alloy (44%:56%), triphenylsilyl chloride, and triethylgallium were purchased from Strem chemicals. Arsenic powder was purchased from Atomergic Chemetals. *tert*-Butyldimethylsilyl chloride was purchased from Aldrich Chemicals and used as received.  $^1\text{H}$  and  $^{13}\text{C}\{^1\text{H}\}$  NMR spectra were recorded on a Varian XL-300 spectrometer operating at 300 and 75.4 MHz, respectively and a Varian Unity 400 spectrometer operating at 400 and 100.6 MHz, respectively.  $^1\text{H}$  and  $^{13}\text{C}\{^1\text{H}\}$  spectra were referenced to TMS by using the residual protons or carbons of deuterated benzene at  $\delta$  7.15 or 128 ppm, respectively, or the upfield pentet of  $\text{C}_7\text{D}_8$  at  $\delta$  2.09 ppm for the  $^1\text{H}$  NMR spectra. All NMR samples were prepared in 5-mm tubes which were flame-sealed under vacuum or septum-sealed under argon. Melting points (uncorrected) were obtained with a Thomas-Hoover Uni-melt apparatus, and capillaries were flame-sealed under argon. Elemental Analyses were performed by E+R Microanalytical Laboratory, Inc., Corona, NY. Mass spectral data were collected on a JEOL JMS-SX 102A spectrometer operating in the electron ionization mode at 20 eV. X-ray crystallographic data were obtained as described (*vide infra*).

### *Preparation of As(Si<sup>i</sup>BuMe<sub>2</sub>)<sub>3</sub> (1)*

Sodium-potassium alloy (2.514 g, 84.08 mmol) was transferred *via* pipet to a 50 mL addition bulb, which was attached to a 1L round-bottomed screw-top flask equipped with a Teflon valve and magnetic stirbar. A second 50 mL addition bulb attached to the 1L flask was charged with <sup>i</sup>BuMe<sub>2</sub>SiCl (12.666 g, 84.08 mmol) dissolved in 40 mL of DME. Arsenic powder (2.000 g, 26.69 mmol) was added to the 1 L reaction bulb along with 450 mL of DME. The flask was removed from the dry-box and placed in an oil bath. The arsenic suspension was heated to 65 °C with stirring and the sodium-potassium alloy was added over a 2 min. period. The resulting black suspension was heated at 65 °C for 6.5 h, followed by cooling to room temperature and addition of the <sup>i</sup>BuMe<sub>2</sub>SiCl solution dropwise over a 1.5 h period. The black mixture was heated at 82 °C for 22 h where a black to olive-green color change was observed. Cooling the reaction mixture, followed by filtration and concentration of volatiles *in vacuo*, afforded several colorless X-ray quality crystals of **1**. Complete recovery of **1** was achieved by removal of the remaining volatiles, followed by sublimation and recrystallization of the white solid obtained. Yield (1.23 g, 10.9%). mp. 156-158 °C. Anal. Calcd. (found) for C<sub>18</sub>H<sub>45</sub>AsSi<sub>3</sub>: C, 51.39 (51.41); H, 10.78 (10.79). <sup>1</sup>H NMR (C<sub>6</sub>D<sub>6</sub>): δ 0.39 (s, -Me<sub>2</sub>), 1.05 [s, -CMe<sub>3</sub>]. <sup>13</sup>C{<sup>1</sup>H} NMR (C<sub>6</sub>D<sub>6</sub>): δ 1.85 [s, -Si(CH<sub>3</sub>)<sub>3</sub>] 27.82 [s, -C(CH<sub>3</sub>)<sub>3</sub>].

### *Preparation of As(SiMe<sub>3</sub>)<sub>2</sub>(SiPh<sub>3</sub>) (2)*

Ph<sub>3</sub>SiCl (2.944 g, 10.00 mmol) dissolved in 25 mL of diethyl ether was added *via* pipet to a 50 mL addition bulb, which was attached to a 500 mL round-bottomed screw-top flask equipped with a Teflon valve and magnetic stirbar. LiAs(SiMe<sub>3</sub>)<sub>2</sub> (2.282 g, 10.00 mmol) was added to the 500 mL reaction bulb along with 50 mL of diethyl ether. The flask was removed from the dry-box and placed into an ice bath. The Ph<sub>3</sub>SiCl solution was added dropwise to the stirring LiAs(SiMe<sub>3</sub>)<sub>2</sub> solution over a one hour period, resulting in the formation of a white precipitate from solution. The cloudy mixture was

stirred at room temperature for 24 h. Filtering the solution and removing the volatiles *in vacuo* afforded a pale yellow solid which was extracted into 10 mL of warm pentane. Cooling the extract to -30 °C for 2 d afforded colorless crystals of **2** suitable for X-ray analysis (4.210 g, 87.4%). mp. 81 - 85 °C. Anal. Calcd. (found) for C<sub>24</sub>H<sub>33</sub>AsSi<sub>3</sub>: C, 59.97 (60.06); H, 6.92 (6.89). <sup>1</sup>H NMR (C<sub>6</sub>D<sub>6</sub>): δ 0.21 (s, -SiMe<sub>3</sub>), 7.08 (m, -SiPh<sub>3</sub>), 7.86 (m, -SiPh<sub>3</sub>). <sup>13</sup>C{<sup>1</sup>H} NMR (C<sub>6</sub>D<sub>6</sub>): δ 4.30 (s, -SiMe<sub>3</sub>); 128.10, 129.66, 136.72 (s, -SiPh<sub>3</sub>).

#### *Preparation of Et<sub>3</sub>Ga•As(SiMe<sub>3</sub>)<sub>2</sub>(SiPh<sub>3</sub>) (3)*

Et<sub>3</sub>Ga (0.157 g, 1.00 mmol) dissolved in 25 mL of pentane was added *via* pipet to a 250 mL round-bottomed screw-top flask equipped with a Teflon valve and magnetic stirbar. Compound **2** (0.482 g, 1.00 mmol) dissolved in 25 mL of pentane was added *via* pipet to the stirring Et<sub>3</sub>Ga solution. The resulting cloudy solution was stirred at room temperature for 4 d. Removal of the volatiles *in vacuo* yielded a white-crystalline solid which was dissolved in 5 mL of warm toluene. Cooling the extract to -30 °C for several days afforded colorless hexagonal crystals of **3** suitable for X-ray analysis (0.447 g, 70%). mp. 107-110 °C. Anal. Calcd. (found) for C<sub>30</sub>H<sub>48</sub>AsGaSi<sub>3</sub>: C, 56.51 (56.72); H, 7.59 (7.67). <sup>1</sup>H NMR (C<sub>6</sub>D<sub>6</sub>): δ 0.21 (s, -SiMe<sub>3</sub>), 0.58 [q, -CH<sub>2</sub> (<sup>3</sup>J<sub>H-H</sub> = 8 Hz)], 1.27 [t, -CH<sub>3</sub> (<sup>3</sup>J<sub>H-H</sub> = 8 Hz)], 7.08 (m, -SiPh<sub>3</sub>), 7.81 (m, -SiPh<sub>3</sub>). <sup>13</sup>C{<sup>1</sup>H} NMR (C<sub>6</sub>D<sub>6</sub>): δ 4.01 (s, -Si(C<sub>6</sub>H<sub>5</sub>)<sub>3</sub>), 9.04 (s, -CH<sub>2</sub>), 10.54 (s, -CH<sub>3</sub>); 127.64, 129.71, 136.61 (s, -SiPh<sub>3</sub>).

#### *Preparation of As(SePh)<sub>3</sub> (4)*

In(SePh)<sub>3</sub> (1.07 g, 1.84 mmol) dissolved in 50 mL of toluene was added to a 250 mL round-bottomed flask equipped with a ground-glass valve and a magnetic stirbar. As(SiMe<sub>3</sub>)<sub>3</sub> (0.54 g, 1.84 mmol) was added dropwise *via* syringe to the stirring In(SePh)<sub>3</sub> suspension. After complete addition of the As(SiMe<sub>3</sub>)<sub>3</sub>, a red precipitate

formed from solution. The resulting red mixture was allowed to stir outside of the dry-box for 24 h at room temperature. After 24 h, the stirring was stopped and the red precipitate settled to the bottom of the flask leaving a yellow solution. The yellow solution was transferred *via* canula to an empty 250 mL round-bottomed flask, and the volatiles were removed *in vacuo* yielding a yellow solid which was extracted with 30 mL of pentane. Cooling the extract to -4 °C for 12 h afforded yellow crystals of **4** suitable for X-ray analysis (0.099 g, 10% yield based on As). The <sup>1</sup>H NMR, mass spectral, and melting point data for **4** matched exactly with data reported in a previous literature preparation of As(SePh)<sub>3</sub> [4], thereby confirming its identity.

#### *X-Ray Crystal Structure Determination*

[Crystallographic data for compounds **1** - **4** are summarized in Table 1.]

**Compound 1:** X-ray data were collected on an Enraf-Nonius CAD-4 diffractometer utilizing graphite-monochromated Cu-K $\alpha$  ( $\lambda$  = 1.5418 Å) radiation. Colorless crystals of **1** suitable for X-ray diffraction were mounted inside glass capillaries under argon. Preliminary unit-cell parameters and space group information were derived from oscillation and Weissenberg photographs. The space group was defined uniquely by the systematic absences: 0k0 when  $k \neq 2n$ , h0l when  $l \neq 2n$ . Refined unit-cell parameters were derived from the diffractometer setting angles for 25 reflections (35° < Θ < 40°) widely separated in reciprocal space. Intensity data were corrected for the usual Lorentz and polarization effects; an empirical absorption correction was also applied. The crystal structure was solved by the heavy-atom approach. Initial coordinates for the arsenic atom were derived from a Patterson map. A series of  $F_0$  and difference-Fourier syntheses, phased successively by an increasing number of atoms, yielded coordinates for the silicon and carbon atoms. Atomic positional and thermal parameters of the non-hydrogen atoms (at first isotropic, then anisotropic) were adjusted by means of several rounds of full-matrix least-squares calculations. Hydrogen atoms were incorporated at

their calculated positions (C-H = 1.05 Å) during the later iterations, and an extinction correction was included as a variable during the final cycles. The parameter refinement converged at  $R = 0.068$  ( $R_w = 0.092$ ). A final difference-Fourier synthesis contained no unusual features. Crystallographic calculations were performed on PDP11/44 and MicroVAX computers by use of the Enraf-Nonius Structure Determination Package (SDP). For all structure-factor calculations, neutral atom scattering factors and their anomalous dispersion corrections were taken from ref. 7. Selected interatomic distances and angles are given in Tables 2 and 3, respectively; selected fractional atomic coordinates are listed in Table 4. An ORTEP [8] diagram showing the solid-state conformation and atom numbering scheme of **1** is presented in Figure 1.

*Compounds 2 and 4:* X-ray data were collected on a Rigaku AFC6/S diffractometer utilizing graphite-monochromated Mo-K $\alpha$  ( $\lambda = 0.71073$  Å) radiation. The crystals used were mounted on a glass fiber with a viscous oil under a stream of cold dinitrogen. X-ray intensity data were recorded at -120 °C, and the structures were solved by direct methods. Full-matrix least-squares refinement with weights based upon counter statistics was performed. Hydrogen atoms were incorporated at their calculated positions using a riding model in the later iterations of refinement which converged at  $R = 0.033$  ( $R_w = 0.035$ ) for **2** and  $R = 0.045$  ( $R_w = 0.054$ ) for **4**. A final difference-Fourier synthesis revealed no unusual features. Crystallographic calculations were performed using the NRCVAX [9] suite of structure determination programs. The space group choices for **2** and **4** were confirmed by the MISSYM [10] missing symmetry treatment program. For all structure-factor calculations, neutral atom scattering factors and their anomalous dispersion corrections were taken from ref. 7. Selected interatomic distances and angles are given in Tables 2 and 3, respectively; selected fractional atomic coordinates are listed in Table 4. ORTEP [8] diagrams showing the solid-state

conformations and atom numbering schemes of **2** and **4** are presented in Figures 2 and 4, respectively.

**Compound 3:** X-ray data were collected at 25 °C on a Siemens P4 diffractometer utilizing graphite-monochromated Mo-K $\alpha$  ( $\lambda = 0.71073 \text{ \AA}$ ) radiation. Colorless crystals of **3** suitable for X-ray diffraction were mounted inside glass capillaries under argon. The unit-cell parameters were obtained by the least-squares refinement of the angular settings of 24 reflections ( $20^\circ < 2\Theta < 25^\circ$ ). The structure was solved by direct methods, completed by subsequent difference-Fourier syntheses and refined by full-matrix least-squares procedures. All non-hydrogen atoms were refined anisotropically, and hydrogen atoms were treated as idealized contributions. All software and sources of the scattering factors are contained in the SHELXTL PLUS [11] (4.2) and SHELXTL (5.3) program libraries. Selected interatomic distances and angles are given in Tables 2 and 3, respectively; selected fractional atomic coordinates are listed in Table 4. An ORTEP [8] diagram showing the solid-state conformation and atom numbering scheme of **3** is presented in Figure 3.

[Full information concerning conditions for crystallographic data collection and structure refinement, atomic coordinates, bond lengths and angles, thermal parameters, and observed and calculated structure factors for **1 - 4** have been deposited with the Cambridge Crystallographic Data Centre.]

## RESULTS AND DISCUSSION

The 1:3 mole reaction of (Na/K)<sub>3</sub>As with <sup>t</sup>BuMe<sub>2</sub>SiCl affords the crystalline silylarsine As(Si<sup>t</sup>BuMe<sub>2</sub>)<sub>3</sub> (**1**) in a low yield. A similar method was first used by Becker, *et al.* to prepare As(SiMe<sub>3</sub>)<sub>3</sub> [6a], however, the product isolated is a liquid. By

incorporating the bulky  $^t\text{BuMe}_2\text{Si}$  groups around the As center, we were able to isolate compound **1** as a crystalline material, and it was characterized by  $^1\text{H}$  and  $^{13}\text{C}\{^1\text{H}\}$  NMR spectroscopy, partial elemental analysis, and single-crystal X-ray analysis (*vide infra*).

Reaction of  $\text{LiAs}(\text{SiMe}_3)_2$  with  $\text{Ph}_3\text{SiCl}$  (1:1) yields  $\text{As}(\text{SiMe}_3)_2(\text{SiPh}_3)$  (**2**) in a good crystalline yield. As is seen for **1**, incorporating the relatively bulky  $\text{Ph}_3\text{Si}$  group around the As center allows the resulting trisilylarsine to exist as a crystalline compound. The phosphorus analog of **2** was previously reported by Power and co-workers [12], but, they did not address any chemistry relating to the arsenic species.

To examine the reactivity of **2** toward Group 13-metal compounds, the 1:1 mole reaction of **2** with  $\text{Et}_3\text{Ga}$  was carried out at room temperature, yielding the simple adduct  $\text{Et}_3\text{Ga}\bullet\text{As}(\text{SiMe}_3)_2(\text{SiPh}_3)$  (**3**). This result is in contrast to those observed in similar reactions of **1**, where attempted silyl-elimination and Lewis acid-base adduct formation reactions utilizing **1** and a Group 13-metal compound were unsuccessful. In addition, during these studies, we noted that as the ligand size was increased on the Group 13 center, compound **2** failed to form adducts analogous to **3**. It is interesting to note that compound **3**, with its ethyl substituents on the metal center, has great potential to serve as a single-source precursor to  $\text{GaAs}$  through a facile  $\beta$ -hydride/organosilane elimination pathway.

The tris(seleno)arsine  $\text{As}(\text{SePh})_3$  (**4**) was the only isolable crystalline product from the 1:1 reaction of  $\text{In}(\text{SePh})_3$  and  $\text{As}(\text{SiMe}_3)_3$  and was recovered in a very low yield (~10%). The exact pathway to the formation of **4** is unclear, however, the low yield suggests the presence of other oligomeric species which we could not isolate and characterize. Ligand redistributions of this type are not without precedent in 13-15 chemistry and have been observed in a variety of systems [13]. Compound **4** was previously prepared by Barton, *et al.* [4a] and by Dean and co-workers [4b] by the direct 3:1 reaction of  $\text{NaSePh}$  and  $\text{AsCl}_3$ , but, no solid-state structure was reported.

Compound **1** crystallizes in the monoclinic system with four molecules occupying the general positions of the centrosymmetric space group  $P\ 21/c$ . In the solid state, this molecule adopts the conformation depicted in Figure 1. The most noteworthy structural feature of **1** is the pyramidal nature of the  $\text{AsSi}_3$  core, which is evidenced by the average Si-As-Si angle of  $106.5^\circ$ . The average Si-As bond length of  $2.376\ \text{\AA}$  in **1** is in accord with the sum of the covalent radii [14] for these two atoms.

Compound **2** crystallizes in the orthorhombic system with four molecules occupying the general positions of the unit cell. As in **1**, the pyramidal geometry of the  $\text{AsSi}_3$  core is evident as reflected in the average Si-As-Si angle of  $105.0^\circ$ . The greater deviation from ideal tetrahedral coordination geometry in **2** vs. **1** is likely a function of the steric requirements imposed by the  $\text{Ph}_3\text{Si}$  ligand. The average Si-As bond length of  $2.357\ \text{\AA}$  in **2** is only slightly shorter than that observed in **1**.

Crystals of adduct **3** belong to the monoclinic system space group  $P\ 21/c$ . The Ga-As bond length of  $2.694(1)\ \text{\AA}$  in **3** is slightly longer than that usually observed for other adducts of this type [15]. This is not surprising due to the presence of the bulky  $\text{Ph}_3\text{Si}$  ligand. In the solid state, the ethyl substituents on the gallium center and the silyl substituents on the arsenic atom are in a staggered conformation to one another. As shown by the mean Si-As-Ga angle of  $111.8^\circ$  and mean C-Ga-As angle of  $103.2^\circ$  in **3**, the metal and pnicogen centers reside in distorted tetrahedral coordination environments. It is important to note that, to our knowledge, compound **3** represents only the third example of a structurally characterized Ga-As Lewis acid-base adduct.

The tris(seleno)arsine **4** crystallizes in the trigonal system, space group  $R\bar{3}$ . Although structural data for this compound were previously unreported, the adduct  $(\text{PhSe})_3\text{As}\bullet\text{MnCp}'(\text{CO})_2$  ( $\text{Cp}' = \text{C}_5\text{H}_4\text{Me}$ ) (**5**) [16] was fully characterized. The pyramidal  $\text{AsSe}_3$  core in **4** is greatly distorted from the ideal tetrahedral angle, as shown by the Se-As-Se angle of  $95.56(5)^\circ$ . The Se-As bond length of  $2.374(1)\ \text{\AA}$  in **4** is nearly

identical to the sum of the covalent radii [14] for the two atoms as well as that observed in **5**.

#### ACKNOWLEDGMENTS

We wish to thank the Office of Naval Research for their generous financial support.

R. A. B. wishes to thank the Lucent Technologies Bell Laboratories Cooperative Research Fellowship Program for a graduate fellowship.

<sup>a</sup>B<sub>eq</sub> = the mean of the principal axes of the thermal ellipsoid

TECHNICAL REPORT DISTRIBUTION LIST - GENERAL

Office of Naval Research (1)  
Chemistry Division, ONR 331  
800 North Quincy Street  
Arlington, Virginia 22217-5660

Dr. Richard W. Drisko (1)  
Naval Facilities & Engineering  
Service Center  
Code L52  
Port Hueneme, CA 93043

Defense Technical Information  
Center (2)  
Building 5, Cameron Station  
Alexandria, VA 22314

Dr. James S. Murday (1)  
Chemistry Division, Code 6100  
Naval Research Laboratory  
Washington, D.C. 20375-5320

Dr. Eugene C. Fischer (1)  
Code 2840  
Naval Surface Warfare Center  
Carderock Division Detachment  
Annapolis, MD 21402-1198

Dr. John Fischer, Director (1)  
Chemistry Division, C0235  
Naval Air Weapons Center  
Weapons Division  
China Lake, CA 93555-6001

Dr. Bernard E. Douda (1)  
Crane Division  
Naval Surface Warfare Center  
Crane, Indiana 47522-5000

Dr. Peter Seligman (1)  
Naval Command, Control and  
Ocean Surveillance Center  
RDT&E Division  
San Diego, CA 92152-5000
